

Breast Cancer Risk in Relation to Ambient Air Pollution Exposure at Residences in the Sister Study Cohort

Kerryn W. Reding^{1,2}, Michael T. Young³, Adam A. Szpiro³, Claire J. Han¹, Lisa A. DeRoo⁴, Clarice Weinberg⁵, Joel D. Kaufman³, and Dale P. Sandler⁵

Abstract

Background: Some but not all past studies reported associations between components of air pollution and breast cancer, namely fine particulate matter ≤ 2.5 μm ($\text{PM}_{2.5}$) and nitrogen dioxide (NO_2). It is yet unclear whether risks differ according to estrogen receptor (ER) and progesterone receptor (PR) status.

Methods: This analysis includes 47,591 women from the Sister Study cohort enrolled from August 2003 to July 2009, in whom 1,749 invasive breast cancer cases arose from enrollment to January 2013. Using Cox proportional hazards and polytomous logistic regression, we estimated breast cancer risk associated with residential exposure to NO_2 , $\text{PM}_{2.5}$, and PM_{10} .

Results: Although breast cancer risk overall was not associated with $\text{PM}_{2.5}$ [HR = 1.03; 95% confidence intervals (CI), 0.96–1.11], PM_{10} (HR = 0.99; 95% CI, 0.98–1.00), or NO_2 (HR = 1.02;

95% CI, 0.97–1.07), the association with NO_2 differed according to ER/PR subtype ($P = 0.04$). For an interquartile range (IQR) difference of 5.8 parts per billion (ppb) in NO_2 , the relative risk (RR) of ER^+/PR^+ breast cancer was 1.10 (95% CI, 1.02–1.19), while there was no evidence of association with ER^-/PR^- (RR = 0.92; 95% CI, 0.77–1.09; $P_{\text{interaction}} = 0.04$).

Conclusions: Within the Sister Study cohort, we found no significant associations between air pollution and breast cancer risk overall. But we observed an increased risk of ER^+/PR^+ breast cancer associated with NO_2 .

Impact: Though these results suggest there is no substantial increased risk for breast cancer overall in relation to air pollution, NO_2 , a marker of traffic-related air pollution, may differentially affect ER^+/PR^+ breast cancer. *Cancer Epidemiol Biomarkers Prev*; 24(12); 1907–9. ©2015 AACR.

Introduction

Several studies suggest an association between breast cancer risk and exposure to ambient fine-particulate matter ($\text{PM}_{2.5}$) and nitrogen dioxide (NO_2), a marker of traffic-related air pollution (1–3). Most notably, a 2010 case-control study reported a 1.3-fold increased risk of breast cancer [95% confidence intervals (CI) of OR: 1.0–1.7] for every 5 ppb increase in NO_2 assessed via a land-use regression spatial model (3). The California Teachers Study recently reported an increased risk for ER^-/PR^- breast cancer associated with endocrine disruptors present in ambient air, namely cadmium compounds and inorganic arsenic (4). However, to date, relatively few studies have investigated the link between air pollution and breast cancer subtypes. This analysis sought to investigate breast cancer risk in relation to primary

components of air pollution, namely $\text{PM}_{2.5}$, PM_{10} , and NO_2 , and potential risk differences by breast cancer subtype.

Materials and Methods

The Sister Study, a cohort of 50,884 U.S. women between ages 35 to 74 whose sister had breast cancer (5), enrolled participants from August 2003 to July 2009, who were followed for a mean of 4.95 years. Two thousand and eighty-nine breast cancer cases arose between enrollment and January 2013, (of which 316 were *in situ*), with a mean time to breast cancer of 3.96 years. Air pollution exposure was not ascertained on 1,234 women (24 invasive and 6 *in situ*; 1,204 noncases) predominantly because they lived outside the conterminous U.S., resulting in 1,749 invasive breast cancers and 47,591 noncases for this analysis. Annual averages of air pollution concentration outside the residence were estimated at each participant's home from a validated regionalized universal kriging model derived from regulatory monitors and a large suite of geographic covariates using previously described methods (6). For primary analyses, air pollution estimates were based on annual average concentrations at baseline home addresses, derived using monitoring data from 2006 ($\text{PM}_{2.5}$ and NO_2) and 2000 (PM_{10}). The cross-validated R^2 for $\text{PM}_{2.5}$, NO_2 , and PM_{10} were 0.88, 0.85, and 0.53, respectively (6). HR and 95% CI were estimated using Cox proportional hazards models. Known breast cancer risk factors were considered for inclusion in the model if the factor was associated with both air pollution and breast cancer. Race, educational attainment, smoking status, and menopausal hormone therapy met these criteria.

^aExcluding *in situ* breast cancer cases.

Results were unchanged when we adjusted for geography using splines. In subset analyses, (i) we examined the effect of air pollution separately for breast cancer subtypes, stratifying by estrogen receptor/progesterone receptor (ER/PR) and stage, calculating RR and 95% CI using polytomous logistic regression; and (ii) we examined residential air pollution concentrations derived from 1990's estimates among those who had lived long-term at

their current residence (i.e., excluding those who changed residences) in order to investigate associations of long-term air pollution with breast cancer.

Results

Breast cancer cases were more likely White, highly educated, and users of menopausal hormone therapy (Table 1). There was no association between invasive breast cancer overall and PM_{2.5}, PM₁₀, or NO₂ (Table 2). However, the risk associated with NO₂ differed when stratified by ER/PR ($P = 0.04$). NO₂ was associated with a 1.10-fold increased risk of ER⁺/PR⁺ breast cancer [95% CI, 1.02–1.19 per interquartile range (IQR) of 5.8 ppb] but not with ER⁻/PR⁻ breast cancer (RR = 0.92; 95% CI, 0.77–1.09). We observed a borderline increased risk of breast cancer *in situ* in relation to NO₂ (HR = 1.10; 95% CI, 0.99–1.24 per IQR of 5.8 ppb; data not shown).

Discussion

Our analysis did not suggest an association between air pollution and overall invasive breast cancer risk. Multiple studies (2, 3), but not all (4, 7), found that exposure to traffic-related air pollutants, particularly NO₂, increased breast cancer risk. A potential explanation for differences among studies could be differing proportions of ER/PR subtypes, if as our data suggest, NO₂ is only associated with ER⁺/PR⁺ breast cancer. NO₂ probably serves as a marker for traffic-related pollution rather than a causal factor *per se* (3). As such, it may serve as a proxy for components of air pollution that affect estrogens, such as polycyclic aromatic hydrocarbons (PAH). PAHs have estrogenic properties, as shown by PAH binding to ER-β to induce transcriptional targets (8). Thus, there is biologic plausibility for a differential role of air pollution by hormone receptor status. However, Liu and colleagues reported that estrogen disruptors in ambient air were not associated with ER⁺/PR⁺, but rather with ER⁻/PR⁻ breast cancer (their analysis did not report on NO₂; ref. 4).

This analysis using a prospective, large national sample that systematically evaluated air pollution using state-of-the-art spatial modeling is able to rule out a strong relationship between air pollution and breast cancer risk. One limitation is that air pollution exposure earlier in life could affect breast cancer risk; however, our analysis of long-term air pollution exposure showed results were unchanged. Replication of these results is needed before firm conclusions can be drawn regarding ER⁺/PR⁺ breast cancer risk in relation to traffic-related air pollution.

Table 2. The risk of invasive breast cancer associated with PM_{2.5}, PM₁₀, and NO₂

Air pollution	Control (N = 47,591)		Breast cancer				ER ⁺ /PR ⁺ (N = 947)		Breast cancer subtype				P ^e		
	Mean	SD	All cases (N = 1,749)		HR ^{a,b,c}	95% CI	Mean	SD	ER ⁻ /PR ⁻ (N = 223)		RR ^{b,c,d}	95% CI			
			Mean	SD					Mean	SD					
PM _{2.5}	10.5	2.4	10.5	2.4	1.03	0.96–1.11	10.4	2.4	1.00	0.91–1.09	10.5	2.5	0.99	0.81–1.20	0.99
